Florida Clumping Bamboo Nitrogen Recommendations

We believe that fertigation plays an important role in Bamboo production, especially during the summer rainy months. Smaller periodic spoon feedings throughout the heavier growing cycle is important for optimizing growth and production of shoots. Another benefit is reducing the opportunity for nutrient loss due to run off. We recommend an 8-2-8 for a NPK blend or 32% UAN or 21% AN if wanting to only put out nitrogen. See the following rates and application windows below, assuming microjet irrigation is present.

8-2-8 Liquid

- April – August application
- 1 – application per month
- 10 gallons per acre

32% UAN Liquid

- April – August applications
- 1 – application per month
- 5 gallons per acre

21% AN Liquid

- April – August applications
- 1 – application per month
- 5 gallons per acre
